

MIRA - Recovery and Handoff Evidence

Purpose

Test whether an interrupted ingestion workflow can resume from saved checkpoint context with approval and replay safeguards.

Work tested

A targeted automated test exercised interrupted ingestion, checkpointed helper/actor continuation, a human-approval gate and a traceable handoff result.

Recorded outcome

The saved report records one test passed and three deselected. It reports that checkpoint state supported resumption, approval was enforced and satisfied, helper/actor context continued, repeated events did not add duplicate semantic rows, and the handoff outcome was recorded.

What this supports

A bounded automated check of recovery, approval and replay safety. It adds continuity evidence beyond the earlier fixed-task Hello World pilot.

Source basis

Saved MIRA Ingestion Recovery Proof report. Test: `test_recover_interrupted_ingestion_job_with_checkpointed_helper_switch_and_handoff` in `tests/test_provenance_ingestion.py`. The original text report remains available alongside this PDF.

Limits

Historical local automated-test evidence; not rerun for this portfolio update. This does not establish live switching between external LLMs, automatic coordination of separate chat applications, production scale or unattended orchestration. The earlier Hello World execution pilot is a separate milestone.
